TECHNICAL REPORT OF THE PRELIMINARY FINDINGS
OF THE INFORMAL SURVEY, 1989 - 90
HILLSIDE AGRICULTURE SUB-PROJECT

PREFACE

Since the last quarter of 1989, the Informal Survey has been
 carried out in the North - Eastern hillsides of St.
 Catherine. Consequently, this report presents the
 preliminary findings of the exercise as well as implications
 for the project implementation activities.

The report is comprised of five sections: (1) the Survey
 Process, (2) Presentation of Actual Findings, (3) Examination
 of Main Trends, (4) Conclusion and Recommendations and (5)
 the Appendices.

In section I, the various components of the initial planning
 stage and the data collection/processing exercises are
 outlined. Emphasis is placed on the explanation of the
 survey's objectives, methodology and administration.

In section II, there is an outline of the survey's results.
 They are given in a summary form, with the information
 grouped in the following categories, Farmer Social
 Characteristics, Land Resources, Agricultural Support
 Services, Crop Production Systems and Farming Problems.

A more detailed statistical analysis of these preliminary
 findings can be found in the third section. The information
 is grouped along similar lines as in the previous section.

Conclusions are drawn in Part IV, based on the preliminary
 findings presented earlier in the report. Also, recommendations
 for implementation strategies, (particularly in reference to
 the On-Farm Trials) are given.

Supplementary material, primarily, Project Area Maps, sample
 questionnaire as well as a glossary of the technical terms
 are included in the final section, the Appendices.
Part I
The Survey Process

1. Background

The main goals of the Hillside Agriculture Sub-Project are embodied within its official title, ‘Improving Watershed Management and Increasing Socio-economic Well Being through Farming Systems Research and Development’. [1]

The project’s activities have been aimed at creating economically viable hillside agricultural production systems, increased sustainable small farmer income, rational resource conservation as well as strengthened farmer organizations for the residents of the Northern Rio Cobre Watershed. [2]

The Informal Survey launched the implementation phase in Mid-October, 1989. Although, planned originally as a two week Reconnaissance exercise, it has become an on-going data collection tool. Challenges faced during the initial stages included the unfamiliarity of the project staff to the terrain, gradual addition of new staff, difficulty in locating farmers and on-going simultaneous activities (project promotion and formation of twelve Farmers Action Committee Teams).

Despite these difficulties, the initial target of completing two hundred and fifty (250) questionnaires was surpassed. In fact, over three hundred (300) farmers had been interviewed.

2. Survey Objectives

The objectives were two-fold in nature. Firstly, to provide a diagnosis of the local farming environment and constraints. Such information would be later analyzed and published for the benefit of the Sub-Project.

Secondly, it was a pilot study or rather, a pre-runner to the formal Baseline Survey (as required by the project document). Hence, project planners would get a realistic idea, pertaining to: deadlines, cost estimates and personnel requirements, associated with the execution of Surveys in the area.

[1] HASP is executed by the Research and Development Division, Ministry of Agriculture with USAID funds, which are administered by the Inter-American Institute for Cooperation on Agriculture (IICA).

[2] The area is composed of five Extension Areas bounded by Seafield in the North, Troja in the East, Riversdale in the South and Redwood in the West.
3. Methodology

The absence of a probability sample gave the survey its informal nature. The original sampling frame, the Ministry's Farmers Register proved to be inadequate in terms of current information on the location and distribution of farmers. Many had died, migrated or just could not be found.

Consequently, a modified format, a combination of Area and Quota Sampling was instead used. The Project Area Map [3] then became the frame. Enumeration was carried out in the districts and sub-districts of the three Administrative Areas [4], Golden Grove, Troja and Riversdale.

Also, the data collection officers [5] were not restricted to the confines of any particular sub-division. However, they were each required to fulfill daily targets.

Interviews were pre-arranged through the newly formed Farmers Action Committee Teams (FACTs groups) in each of the twelve districts. This strategy overcame the difficulty of locating farmers on their holdings.

Questionnaire Design

As shown in Appendix II, this structured schedule was designed to obtain a basic Agro-socio-economic overview of the farming community as well as the availability of support services in the area.

The questions were mostly pre-coded/closed, in order to facilitate future electronic data processing. However, a few were left open-ended, to generate qualitative data on certain aspects, specifically on Soil Conservation and Farm Record-keeping, which the project hoped to develop within the next 4 years.

[5] The Data Collection Officers consisted of the project staff, Agronomists (3), Assistant Agronomist (1), Rural Development Officer (1) and Economist (1).
Common terms and concepts associated with the wording of the schedule, are presented in Appendix III. They are quite useful in aiding the reader's understandings of the Survey's findings.

5. Processing and Analysis

Editing, Coding and Data Entry Operations were performed by the project's staff. Actual processing activities were divided into two phases, manual and electronic. The latter would give more elaborate detailed analysis of the trends.

The main purposes of Data editing were to ensure that crop acreages matched physical farm acreages, as well as the conversion of various production measures to a single standard unit, the pound.

Coding involved assigning four digit identification numbers to individual questionnaires to facilitate sorting procedures. Additional single digit codes were given to holdings (principally, the Main Parcel [6]) located in one of the three administrative areas.

The information was entered initially, on Master Sheets by hand. From this basic database, tables were constructed and later integrated within the preliminary report. At the end of March 1990, approximately two hundred and fifty five (255) questionnaires were processed in this manner.

The rationale for the use of Master Sheets was its timeliness in processing a relatively small survey. In other words, it would enable easier and faster Data Entry activities, in contrast to the time involved in the design and development of a customized Electronic Data Processing environment.

On the other hand, the Master Sheets might generate less accurate results as there would be more room for human intervention throughout all stages of the Entry and Processing operations. Additionally, The Master Sheets do not readily lend themselves to more elaborate and complex analysis.

Part II
Summary of Actual Findings

This section contains a brief outline of the results derived from the Survey. They included the following:

1. SOCIAL CHARACTERISTICS OF THE FARMER(S)
   a. Age
      - Only 15.6% of the farmers were less than 39 years old
   b. Gender
      - Women farmers comprised 8.2% of all the farmers.
      - The median age range for women was 39 - 48, but for men, it was the 59 - 68 age category.
   c. Membership in Farmer Organizations
      - 45.6% of the farmers were members of farmer organizations.
      - 60.7% of the farmers were members of the Jamaica Agricultural Society (JAS).
      - The second most popular grouping was the Cocoa Cooperative with 30.8% of the farmers.
      - Only 4.3% of the farmers were members of the Coffee Cooperative.
   d. Membership and Age
      - Only 9.3% of the farmers in all the organizations were under 39 years.
   e. Record-Keeping
      - Only 12 farmers out of the sample (225) kept some form of records.
2. **LAND RESOURCES**

   a. **Farm Size**
      
      - the overall average farm size was 8.3 acres.
      
      - 40.5% of the farms fell into the 5 to less than 10 acre category.
      
      - 29.8% of the farms were between 2 to less than 5 acres in size.
      
      - less than 10% of the farms were less than 2 acres in size.
      
      - 19.8% of the farms were over 10 acres in size.

   b. **Farm Fragmentation**
      
      - 72.6% of the farmers had 2 or more parcels.
      
      - 35.6% of the sample was more likely to have only 2 parcels.

   c. **Tenure by Parcel**
      
      - 40.4% of the parcels were owned and this proportion accounted for 52.7% of the total farm area.
      
      - 36% of the parcels were held by family members. This accounted for 27.4% of the total farm area.
      
      - 7.4% of the parcels were rented while 7.8% was leased.

   d. **Land Utilization**
      
      - 52.4% of the total farm area was under some form of cultivation, with 39.8% in Tree Crop production and the remaining 12.6% devoted to other crops.
      
      - 41.6% of the total farm acreage was in a Ruinate State.

   e. **Soil Conservation**
      
      - 32.9% of the farmers practiced some form of Soil Conservation.
      
      - Over 73.7% of the farmers involved in this activity, was over 49 years.
      
      - 52.8% of the farmers had Contour Barriers on their land.
      
      - 46.2% of the farmers reported Trenches on their land.
3. AGRICULTURAL SUPPORT SERVICES

3.1. Marketing

a. Outlets and Agents

- Hugglers were the main marketing agents for 54.1% of the farmers.

- Commodity Boards handled the produce of 28.6% of the farmers.

- Nearly 10% of the farmers marketed their own produce directly.

- 7% of the farmers reported their female family members as their main marketing agents.

b. Transportation for Agents

- 51.9% of the farmers reported that Trucks carried their produce to the selling point.

- 37% of the farmers reported Human means as their main form of transportation.

c. Farmstore Distance

- 44.5% of the farmers had to travel between 11 and 15 miles to their usual farmstore.

- 30.5% travelled between 6 to 10 miles to the farmstore.

- Only 14.5% of the farmers travelled less than 6 miles to the farmstore.

3.2. Extension Services

- 42.3% of Cocoa farmers were visited by the Cocoa Industry Board.

- 44.3% of the Coffee farmers were visited by their respective Commodity Boards.
4. CROP PRODUCTION SYSTEMS

4.1. Tree Crop Distribution

- Cocoa could be considered the most cultivated Tree Crop. It was grown by 76.9% of the sample and covered 51.7% of the total tree crop acreage.

- 38% of the sample grew Coffee. 8.5% of the tree crop acreage was devoted to its production.

- Coconut and Citrus farmers accounted for less than 40% of the sample and 11.9% of the tree crop area.

- Banana was grown by 74.9% of the sample and accounted for 25.4% of the total tree crop area.

- Plantain, as a Main ‘Tree Crop was grown by 16.9% of the sample and was planted on 2.5% of the total tree crop area.

4.2. Tree Crop Production, 1989–90

- Roughly 970.6 boxes or 56,294.8 pounds of Cocoa (wet) were produced in this crop year.

- Approximately 133 boxes or 7,980 pounds of Coffee were produced in this crop year.

- About 409,915 pounds of Banana were produced in the year.

- 58,214 pounds of Coconut, 74,234.15 pounds of Citrus and 33,385 pounds of Plantain were produced in this crop year.

4.3. Cash Crop Distribution and Production, 1989–90

- 70 farmers reported reaping a total of 119,899.5 pounds of Eating Cane, the second highest of all production figures.

- 49 farmers reported reaping 25,046 pounds of Yam in this Crop year.

- Other popular cash crops included Pumpkin, Pineapple, Cocode and Sweet Potato.

4.4. Cultural Practices for Tree Crops

a. Shade

- 78% of Cocoa farmers and 73% of Coffee farmers used Shade Tree for their crops.
- Guango was the most common Shade Tree for both Cocoa and Coffee. 38% of Cocoa and 44.5% of Coffee farmers reported the use of this tree.

- Breadfruit and Mango, were the next popular Shade Trees for both Cocoa and Coffee. 43.4% of Cocoa and 27.8% of Coffee farmers used Breadfruit. 24.5% of Cocoa and 16.5% of Coffee farmers used Mango trees.

b. Pruning

- 47% of Cocoa and 40.2% of Coffee farmers reported Pruning.

- 23% of Citrus farmers, 15% of Banana farmers and 6% of Coconut farmers pruned.

c. Use of Chemical Inputs

- Only 11.7% of Cocoa and 18.5% of Coffee farmers fertilized their trees.

- 20% of Citrus, 10.3% of Coconut and 7.3% of Banana farmers fertilized their crops.

- 2% of Cocoa and 9.3% of Coffee farmers sprayed their trees.

- Only one Citrus farmer and 3 Banana farmers used Pesticides on their trees.

5. Farming Problems

- 28.7% of the responses claimed the lack of funds was one of their three main farming problems.

- 14.3% reported Labour Unavailability as one of their three main problems.

- 13.2% reported Input Unavailability as one of the three main problems.

- 10.8% of the responses listed high labour costs, while 8% reported Road/Transport deficiencies as one of their three main problems.
Part III
Analysis of Main Trends

This section has been devoted to an indepth analysis of the trends, presented in the preceding section.

1. SOCIAL CHARACTERISTICS OF THE FARMER

a. Age

Based on the table below, there seemed to be an aging farming community in the project area. Approximately 65.3% of the farmers were over 49 years, with 17.2% of that amount over the age of 69. Such an age structure could affect the rate of adoption for new agronomic practices.

<table>

<td>100.0</td>
<td></td>
</tr>
</tbody>
</table>

On the other hand, the small percentage of farmers under the age forty would suggest some form of outward migration. Hence, one measure of the project's success could be the number of youth remaining as farmers in the community.

b. Gender

The predominance of male farmers reinforced the notion of the gender division of labour on the farms. In other words, men tend to be more involved in production activities and women in marketing.

The female minority of 8.27% would suggest the limited impact of specialized support services on them. However, more research is needed to determine their influence on Farm Management decisions.
c. Age and Gender

The male age distribution reflected the national Farming tendency, with a peak in the 59 - 68 range. This contrasted with the typical age of the female farmer, which fell into the 39 - 48 category.

d. Membership in Farmer Organization

As mentioned earlier in Part II, 45.8% of the farmers were in farmer organizations. As shown in Table 2, the most popular was the Jamaica Agricultural Society (JAS) with approximately 60.7% of the farmers were JAS members, followed by 30.8% in the Cocoa Cooperatives.

<table>

<td>13.7</td>
<td>21.4</td>
<td>27.3</td>
<td>29.0</td>
<td>100.0</td>
<td></td>
</tr>
</tbody>
</table>

The high percentage of farmers in the Cocoa Cooperative suggest some local specialization in Cocoa production. Hence, collaboration with the two main groupings, would form important institutional linkages.

Age distribution in all these groups was skewed in favour of the older farmers. In fact, 29% of all members were over 69 years. However, 31% of the JAS members were in the 59 - 68 age range but 36% of the Cocoa Cooperative members were over 69 years.

This reinforces the necessity of a group approach by the project staff, as an effective way of dissemination information to the farmers. However, an alternate strategy might be needed to reach the youth.
e. Record-Keeping

From the figures available in Table 3, only twelve (12) farmers kept any form of records. This figure was developed from a sample of 255 farmers.

<table>
<thead>
<tr>
<th>Age Group (Years)</th>
<th>Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>19 - 28</td>
<td>-</td>
</tr>
<tr>
<td>29 - 38</td>
<td>1</td>
</tr>
<tr>
<td>39 - 48</td>
<td>5</td>
</tr>
<tr>
<td>49 - 58</td>

</tr>
<tr>
<td>59 - 68</td>
<td>2</td>
</tr>
<tr>
<td>69 +</td>
<td>2</td>
</tr>
<tr>
<td>Total</td>
<td>12</td>
</tr>
</tbody>
</table>

As shown the farmers who most likely kept records were in the 39 - 48 age range. This might be the most receptive group of farmers to the proposed scheme. In the view of this, the project staff would face quite a challenge when introducing the programme to farmers.

2. Land Resources

a. Farm Size

From table 4, 40.5% of the farms were in the 5 - 9.9 acre category. This was in contrast to national tendency with a prevalence of farms under 5 acres. In fact, 39.7% of the farms in the area was under 5 acres. As a result, the overall farm size average was 8.38 acres. There was a lower average for the most popular category, being 7.5 acres.

Table 4

<td>100.0</td>
<td>-</td>
</tr>
</tbody>
</table>

This suggests that land might be readily available for possible expansion in the future. Also, there would be sufficient land area to develop the tree cropping component on most of the farms.

b. Farm Fragmentation

As shown in Table 5, there was a great incidence of fragmentation in the area. Approximately 72.6% of the farmers operated over two parcels of land. However, 35.6% of the said amount had only two (2) parcels.

Table 5
Parcel Distribution for Project Area Farmers

<table>
<thead>
<tr>
<th>No. of Parcels</th>

<td>100.0</td>
</tr>
</tbody>
</table>
This might be a possible constraint to agricultural development in the area, as there would be limited acreages for the establishment of Fruit Tree Orchards. The situation could be more complicated if the distance between parcels was significant. Farm Management decisions such as the choice of crops, might also be affected.

c. Tenure

As the holdings were so fragmented, it was not possible to have a single tenurial status. Table 6 confirmed that most parcels had separate tenurial conditions.

<table>
<thead>
<tr>
<th>Tenure</th>
<th>No. of Parcels</th>
<th>No. of Parcels by %</th>
<th>Area (Acres)</th>
<th>% Acreage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Own</td>

<td>27.5</td>
</tr>
<tr>
<td>Total</td>
<td>646</td>
<td>100.0</td>
<td>2,000.95</td>
<td>100.0</td>
</tr>
</tbody>
</table>

Roughly, 40.4% of the parcels were owned, and accounted for 52.7% of the total farm area. Family held land was the second most popular. It accounted for 36.1% of the parcels as well as 27.4% of the land area. The high incidence of permanent tenurial status, would imply an eligibility of most farms for project participation.

d. Land Utilization

Approximately 52.4% of the land area was under some form of cultivation. A high proportion, of some 39.8%, as shown in Table 7, was under Tree Crop production with the remaining 12.6% devoted to other crop production.
Table 7

</tr>
</tbody>
</table>

The specialization in Tree Crop production could also be inferred from tables on farm size distribution, and parcel tenure. The high degree of farm fragmentation would indicate Tree Cropping as one of the farmers' more popular means of dealing with such a problem.

Since 12.6% of the area was under the cultivation of other crops, intensive land use might also be inferred. The quantity of Cash Crops as shown in Table 15B would imply established inter-cropping and multiple cropping systems.

A disturbing situation was that high proportion of land resources, some 41.6% in ruinate, an amount equivalent to that under Tree Crop production. Casual observation might suggest poor soil/slope conditions as one possible cause.

However, further information from related tables [7] suggested more defined reasons, of a social nature. The underlying factors consisted of the high proportion of aging farmers, as well as farm fragmentation.

e. Soil Conservation

From Table 8, 32.9% of the sample had some form of soil conservation on their holdings. This would suggest a ready pool of farmers which could be developed and expanded.

[7] Table 1, 5, & 19.

</tbody>
</table>

However, this awareness seemed to be confined to the older farmers. In other words, 73.7% of the farmers who conserved the soil were over 49 years. The most likely farmers were 69 and over. The younger farmers should be targeted for such Extension activities.

Table 9
The Various Soil Conservation Methods Used by Project Area Farmers

<td>1.0</td>
</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>106</strong></td>
<td><strong>100.0</strong></td>
</tr>
</tbody>
</table>

The most popular method reported was the Contour Barrier construction. This accounted for 46.2% of the farmers. Qualitative responses on the questionnaire also listed Dead (log, stone) and Live (grass, tree) barriers, with the latter being more common.

Trenching was also popular, as reported by 46.2% of the farmers. The low percentage for Terracing suggested the farmers' preference for economical and simpler conservation measures.
3. AGRICULTURAL SUPPORT SERVICES

3.1. Marketing

a. Outlets and Agents

As indicated in Table 10, there was a dualistic marketing structure in the area. In other words, the distribution agents and outlets were distinct, as determined by the nature of the crop. The Commodity Boards served the Export crops such as Coffee, Cocoa and Citrus while the Hugglers supplied domestic food crops to the Parochial/Curbside markets.

<table>
<thead>
<tr>
<th>Marketing Agents</th>
<th>Number of Responses</th>
<th>% of Responses</th>
</tr>
</thead>

<tr>
<td>Factory Officer</td>
<td>2</td>
<td>0.5</td>
</tr>
<tr>
<td>Total</td>
<td>357 [8]</td>
<td>100.0</td>
</tr>
</tbody>
</table>

From Table 10, 54.1% of the sample listed Hugglers as one of their main marketing agents. This implied sizeable quantities of domestic food crops were traded on the local market. However, nearly 10% of the farmers were directly responsible for both the marketing and production of crops.

Approximately 28.6% of the farmers reported the Commodity Boards, as being responsible for the distribution of their tree [9] crops. Hence, any increase in the production of crops, due to the project influence, could be readily absorbed by these boards.

b. Transport

From Table 11 below, farmers and their marketing agents relied on mechanized means of Transportation. Trucks were the predominant mode and accounted for 52% of the responses. Buses and Taxis were the popular choice for the minority.

[8] This table was based on the responses given to a multi-part question, where many answers were possible. Hence, the number of responses would exceed the number of farmers in the sample.

[9] Qualitative answers from the Question 6 on the questionnaire.
### Table 11
Most Common Means of Transport

</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>260 [10]</strong></td>
<td><strong>100.0</strong></td>
</tr>
</tbody>
</table>

Roughly 37% of the farmers reported Human means of transport. In other words, they had to walk to their various destinations. Such a situation suggests a possible production constraint as there would be limits to the quantity of produce and inputs transported from the farmstore to the farm.

c. Farmstore Distance

The average farmstore could be considered the main market place for inputs, particularly farm chemicals. Hence, it could be assumed that there is a relationship between farmstore distance and selected input usage on hillside farms.

From Table 12, approximately 44.5% of the farmers travelled between eleven (11) to fifteen (15) miles to the store. The second most cited distance was between six (6) to ten (10) miles.

---

[10] Although the sample size was 255, many of the questionnaires had multiple responses to this question.

<td>100.0</td>
</tr>
</tbody>
</table>

These popular distances could possibly affect input costs incurred by the farmers and subsequently, Crop Production costs. It could also affect the Farmers' decision-making behaviour, in terms of the allocation of resources among the various crops. On the other hand, lower prices and better product availability might characterize the more distant farmstores.

3.2. Extension Services

During Survey Design, Extension services were defined in terms of technical advice offered by the officers of Commodity Boards. The underlying premise was the local specialization in export-oriented tree crops.

Hence, Information and Technology flows were measured as farm visits from the officers. A direct relationship was assumed between the frequency of visits and the state of the farmer knowledge of recent practices.

Table 13  
Number of Cocoa and Coffee Farmers Visited by Extension Officers of Commodity Boards

<table>
<thead>

<td>196</td>
</tr>
<tr>
<td>Number visited</td>
<td>83</td>
</tr>
<tr>
<td>% of crop farmers visited</td>
<td>42.3</td>
</tr>
</tbody>
</table>

From Table 13, almost half the number of Cocoa and Coffee farmers were visited by Officers from both Commodity Boards. However, these results were inconclusive as the frequency of the visits as well as farmer satisfaction with the service were not documented. In spite of these omissions, these results suggest a need for collaboration with these agencies.

4. CROP PRODUCTION SYSTEMS

4.1. Tree Crop Distribution

Based on Table 14, Cocoa was cited as the most cultivated tree crop in the area, with 51.7% of the total tree crop area. It accounted for 76.9% of the farmers in the sample. Coffee was second, with 8.5% of the acreage and 38% of the sample farmers.

<td>100.0</td>
</tr>
</tbody>
</table>

However, these figures were substantially less for Coconut and Citrus. Roughly, 26.6% of the sample had Coconut and 12% had Citrus. The acreage devoted to both crops was less than 12%. This might imply that the project area was not major areas for Coconut, Citrus or Coffee cultivation.

Pimento was cultivated as a main Tree Crop by only a small minority, approximately 5.9% of the sample. The total land area devoted to its cultivation was also minimal, in contrast to the other Tree Crop acreages. In other words, it utilized some 1.9% of the total Land area which was in Tree Crop production.

Although Banana and Plantain could not be considered true Tree crops, they were listed among the most popular farmer responses. Banana was the second only to Cocoa, with 25.4% of the total Tree Crop area and cultivated by 74.9% of the sample. Plantain was grown on a much smaller scale, by only 16.9% of the sample and covered 2.5% of the tree crop area.
4.2. Tree Crop Production

At the outset of the Survey, the intention was to use the data generated from Question 6(b) on the Crop Acreages reaped for the computation of the various Productivity figures. With the lack of Farmer responses for this section, the basis for this measurement had to be changed. Consequently, Crop productivity is now determined by the total production divided by the Crop Acreage planted (instead of Crop Acreages Reaped). The implicit assumption here, is that the Farmers reap from the total area planted for that particular crop, irrespective of Parcel distribution.

</tr>
<tr>
<td>Breadfruit</td>
<td>43</td>
<td>-</td>
<td>20,072.00</td>
<td>-</td>
</tr>
</tbody>
</table>

As shown in Table 15A, most of the sampled farmers cultivated Cocoa and Coffee, both of which had the lowest productivity figures among the main reported Perennials. The difference between these figures was rather small, as Production Per Acre could be rounded off to 2 boxes, respectively. However, these findings should not be too surprising, if one takes into account the low level of crop care and maintenance, inferred from the preceding tables.
Regardless of the differences in total production between the two other popular crops, Coconut and Citrus, both productivity levels are over 1,000 pounds of produce per acre. In fact, Citrus has the greater edge, with a difference of nearly 400 pounds. These levels are significant as both crops have smaller crop acreages and less farmers than both Cocoa and Coffee.

Although the project area is no longer a banana export zone, its total production and general productivity levels still remained high. In fact, it was the highest of all the crops. It showed that farmers had not discontinued cultivation. Their reliance on the regular income no doubt played an important part in the cash flow situation of the farms.

Despite the small number of crop farmers and limited acreage, the production level for Plantain was approximately 33,385 pounds. However, its productivity figure was approximately 14 times that of Coffee.

Given the project's emphasis on tree crops such as Pimento, its present production levels were disappointingly low. As shown in Table 15A, there was greater productivity than the other popular crops such as Cocoa and Coffee. However, there is the real need to increase its production levels in the area.

There is a sizable production of Breadfruit in the area, with reported figures of some 20,072 lbs. As it mainly provided shade for Cocoa and Coffee, individual crop acreages were hardly reported. As such, its productivity figures could not be computed.

4.3. Cash Crop Production

It should be noted that yield data could not be obtained from most of the farmers as they were unable to estimate the area reaped and also, the individual acreages planted were not differentiated on the Questionnaire (see Question 5(e) in Appendix B). Hence, productivity measures for the various cash crops could not be determined. The production data presented in Table 15B, are for crop production per farmer. As such, it is not known whether these figures came from only one parcel of land or the whole farm.
Table 15B
Volume of main Cash Crop Production
for Crop Year, 1989 - 90

<table>
<thead>
<tr>
<th>Main Cash Crop</th>

<td>1,808.00</td>
</tr>
<tr>
<td>Sweet Potato</td>
<td>13</td>
<td>5.1</td>
<td>1,706.00</td>
</tr>
</tbody>
</table>

As shown in the table above, the project area could be considered to be a Sugar Cane area. It had the highest production levels, four times that of the nearest crop, Yam. Yam was another important Cash crop for nearly 20% of the farmers. It had the second highest total production figures of all the reported Cash crops. The remaining 21,118 pounds of Cash crop produce were distributed among Pumpkin, Coccoe Pineapple and Sweet Potato. Therefore, they could be considered minor cash crops in the typical crop mix.

4.4. Cultural Practices

Farmer responses for the knowledges of cultural practices for the two major tree crops, Cocoa, and Coffee were sufficient enough for detailed analysis. On the other hand, inadequate reports were received for the other tree crops, Coconut and Citrus. As such, results for them could be considered to be inconclusive.

a. Shade

Based on Table 16A, less than a quarter of both Cocoa and Coffee farmers had no shade for their crops. This was one of the few practices for which farmers followed the recommending guidelines by the Commodity Boards.

Table 16A
Number of Cocoa and Coffee Farmers
With Shade Trees

<td>3.1</td>
</tr>
<tr>
<td>Apple</td>
<td>4</td>
<td>2.0</td>
<td>4</td>
<td>4.1</td>
</tr>
</tbody>
</table>

Guango was used as the most popular shade by 50.5% of Cocoa and 46.4% of Coffee farmers. However, this tree was once considered an undesirable shade tree for Cocoa.

Breadfruit was the second most popular, as it was used by 43.4% and 27.8% of Cocoa and Coffee farmers, respectively. Mango, one of the project proposed Fruit Tree was used by 24.5% of the Cocoa and 16.5% of the Coffee farmers. There were other less popular shade trees such as Ackee, Cedar and Apple.

b. Pruning
As shown in Table 17, approximately half of Cocoa and Coffee farmers reported doing this exercise. This proportion was in contrast to the other crops, where the reported incidence was significantly lower.

<table>
<thead>
<tr>
<th>Cultural Practices on Main Tree Crops (Number of Farmers)</th>
</tr>
</thead>
<tbody>
<tr>
<td>CULTURAL PRACTICES</td>

</tr>
<tr>
<td>Cocoa</td>
</tr>
<tr>
<td>Coffee</td>
</tr>
<tr>
<td>Coconut</td>
</tr>
<tr>
<td>Citrus</td>
</tr>
<tr>
<td>Banana</td>
</tr>
</tbody>
</table>
There are other factors (not captured by the Survey,) which could influence the effect of this farming activity on the state of the fields. They could include, the regularity and last date of Pruning. Qualitative responses in another project forum [14], suggested pruning was done on an irregular basis.

c. Use of Chemical Inputs

Only a minority of the tree crop farmers reported the use of chemical inputs. Farmers were more likely to use fertilizer on their crops, rather than pesticides. From Table 17, 20% of Citrus farmers applied Fertilizers to their crop. This was the highest proportion of farmers for all the Tree crops, who performed this exercise. Coffee farmers, was the second most likely group to fertilize their trees. The worst case was for Banana, where only 7.3% used fertilizers.

Coffee farmers were also the most likely group of farmers to use Pesticides. This figure of 9.3% was still very low. However, 2% of all Cocoa and 3% of all Banana and only one Citrus farmer did any form of spraying on their crops.

Therefore, one could conclude that cash expenses for the maintenance of these crops were at best minimal. It should be no surprise if the crop yields were lower than recommended levels.

5. FARMING PROBLEMS

Based on the Project's Farming Systems approach, the farmers participation should be included in all phases of its implementation. Such an omission would handicap its effectiveness. Plans would be based solely from an outsider's view, therefore problems and solutions may be totally different from an insider's perspective.

Hence, Table 19 is included to capture the farmers' perception of his/her Agro-Socio-Economic environment. It is shown on the following page.

Table 19

</tr>
<tr>
<td><strong>Total</strong></td>
<td><strong>704[15]</strong></td>
<td><strong>100.0</strong></td>
</tr>
</tbody>
</table>

As shown in the table above, the farmers suffer from a scarcity of production resources, namely, Credit, Material inputs and Labour. However, the main concern was the lack of funds. It was cited by 28.7% of the sample as one of the three main problems. 14.3% reported labour unavailability and 13.2% reported input scarcity. Another 10.8% of the sample were offset by high labour costs.

Although outsiders might have listed Praedial Larceny and Pest/Disease among the three most common problems, only 8% of farmers viewed them as such. They regarded the poor state of roads and transport as more serious problems.

In concluding, Credit, Labour and Input scarcities appeared to be the main constraints, internal to the typical farming system. The success of the project would depend on its ability to deal with these problems.

[15] It would seem that the number of responses exceeded the sample size. However, these results were based on a three part question. The answers were aggregated, therefore 3 x 255 (sample) would give a maximum limit of 765 responses for this section.
Infrastructural deficiencies, particularly, the state of public roads and transport seemed to be external constraints, impinging on the farm environment. Project staff would also be compelled to accept these conditions. However, these long run constraints could improve if the project succeeds in increasing the socio-economic well being of the farmers in the area.

6. CRITERIA FOR FARMER PARTICIPATION IN ON-FARM TRIALS

From Table 20, most of the farmers seemed willing to participate in the project. However, a reduction of nearly 6% of the farmers who could supply land, time and labour to the project, mirrored the extent of the farmers' ability to cope with the increased labour demands associated with the trials.

<table>
<thead>
<tr>
<th>Selection Criteria</th>
<th>Number of Farmers</th>

<td>Time and Labour</td>
<td>225</td>
<td>88.2</td>
</tr>
<tr>
<td>Land, Time and Labour</td>
<td>222</td>
<td>87.0</td>
</tr>
</tbody>
</table>

Approximately 92.9% of the sample was most willing to provide land for the demonstration sites. This was not surprising, given the high proportion of ruinate land in the area.

Farmers were more reluctant to give of their time and labour. This came against a background of reported labour shortages, high labour costs as well as high degree of land fragmentation. All of these factors represented an increased strain on the farmers' ability to get their routine tasks done.

APPENDIX III

A Glossary of Technical Terms
and Definitions

This section has been devoted exclusively to defining and explaining the technical jargon associated with the Survey Design and Implementation as well as the actual wording of the questionnaire. Terms and concepts have been organized in alphabetical order (regardless of discipline) for ease of reference.
Area Reaped - the area of land from which crops are harvested.

Area Sampling - a type of sample in which the sampling units are individual land areas (segments) which can be defined on a map. The segments cover the entire area to be included in the Survey; the segments do not overlap and in most applications, the boundaries of each segment must be clearly defined so that they can be recognized by enumerators in the field.

Closed Questions - these kind of questions offer a choice of alternation, which may be simple alternatives such as 'yes' or 'no' or 'I don't know'. This method of data collection is quicker since all possible answers are already included on the response schedule and all the interviewer has to do is to identify the category in which the response fits.

Crop Acreage - the actual physical area of land occupied by the crop, bearing in mind the spacing between plants.

Fallow - land which is being rested for the purpose of improving productivity.

Farm - land forming or holding or part of a holding but situated in a single parish. Where as the holding is the overall agricultural production regardless of parish location, the farm refers to that part confined to a single parish.

Farming Systems - the management of farming enterprises according to the dictates of the biological, socio-economic environment and the resources, goals and preferences of rural farm families.

Farmer - an individual rearing one cow or its equivalent of other livestock or cultivating one or more crops on a portion of land not less than half (1/2) an acre for a livelihood.
Holding - unit of agricultural production operated under a single management. This may consist of more than one parcel of land and may be scattered over more than one parish.

Interviewer - person who will be asking the questions to fill the questionnaire.

Land Tenure - conditions under which the holder operates the land i.e., owned, leased in, rented in, rent-free or family land.

Location of Holding - a holding may only be located in one administrative area, that is, wherever the main parcel is located.

Main Parcel - the portion of land on which the farmer earns most of his/her income and spends most of his/her time.

Other Land Uses - land occupied by dwelling/farm houses, idle land and other non-agricultural uses.

Parcel - a continuous area of land, unbroken by land operated by someone else. A parcel is a part of a sub-division of a holding.

Pasture - cultivated or uncultivated grassland used for grazing.

Precoded Questions - see Closed Questions

Probability of Selection - the chance each unit has of being included in the sample.

Probability Sample - a sample in which each element in the population has a known probability of selection.

Questionnaire - see Structured Schedule

Quota Sampling - selection is done on a non-random basis. Once the general characteristics within each stratum are decided, a quota assignment is allocated to each interviewer. It is the interviewer's responsibility to choose the actual sample units to fit the characteristics.
Respondent - all qualified farmers who supply the information to fill the questionnaire.

Ruinate - land which has been used in the past but not presently used over a period of one year due to the lack of resources.

Land which is grown with shrubs, etc., over a long period due to poor soil and steep slopes.

Sample - a part of a population, or a subset from a set of units, which is usually provided by random but sometimes deliberate selection, with the object of investigating properties of the parent population or set.

Sampling Frame - a complete list (or specifications that would establish a complete list) of sampling units that cover a population. It provides access to a population in ways that enable probability sampling.

Sampling Units - units in which a survey population is divided for sampling purposes. They are units subject to random selection.

Survey - an examination of a sample of units, usually human beings, animals or institutions, to estimate characteristics of the total.

Shade - any tree that is deliberately planted for the primary purpose of providing cover for another or one that inadvertently provides cover for the cultivated crop.

Survey population - the population actually sampled (or completely enumerated). It is defined by the sampling frame and the procedure for using it.

Structured Schedule - it consists of a form with a series of questions, which implies uniformity of questions put to respondents.
Target Population - the population, which, given full freedom of choice, one might wish to survey, for practical reasons the population actually surveyed could be different from the target population.

Total Physical Acreage - total area of land that is under the farmers' control. This is the sum of the acreage of all the parcels.

Yield - total production obtained per crop acreage of land reaped.
